

RCUITRY

RAM is the temporary storage space for MPU and is enabled when ZPAGE (Zero enable) is low. When R/WB (from the DB0 thru DB7) at the location addressed by the MPU address bus (AB0 thru AB7). When R/WB is high, the MPU reads the stored data at the addressed location.

The signal RAMSEL, when low, has the effect of swapping pages 2 and 3 within the memory. This allows greater programming flexibility.

The NMI (non-maskable interrupt) counter causes an interrupt at the NMI input of the MPU every 4 msec. The interrupt is derived by dividing 3 KHz by a factor of 12 through counter C5. The interrupt occurs when pin 6 of inverter B5 goes low. During power-up, the NMI counter is disabled by RESET. During Self-Test, the NMI is disabled by TEST.

## POWER INPUT

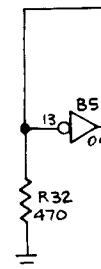

This circuitry consists of the PCB inputs and outputs for the +5 VDC logic power and 36 VAC input to the on board regulators. The +5 VDC inputs and outputs are discussed on Sheet 1, Side A of this schematic set.

The 36 VAC inputs are received by two full wave rectifiers. Diodes CR9 and CR10 rectify the negative cycle of the input and the 7915 regulates the voltage at -15 VDC. Diodes CR11 and CR12 rectify the positive pulse of the 36 VAC input and the 7815 regulates the voltage at +15 VDC. The 7812 regulates at +12 VDC. The 7805 regulates an additional 5 VDC for the DACs. Zener diode CR14 supplies the +8.2 VDC for the sample and hold circuit. The +22V (unregulated) is used to power operational amplifiers P11 and L8 in the audio output.

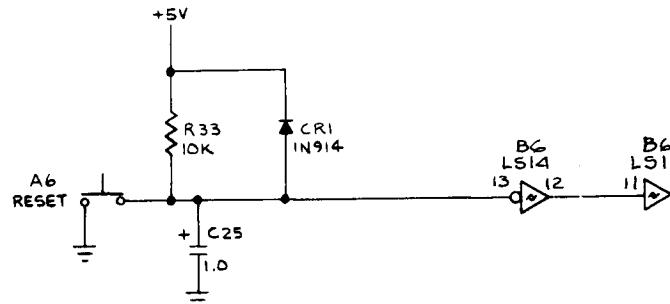

# CLOCK CIRCUIT

The clock circuit consists of two logic inverters and counters C4 and B4. It takes the crystal frequency down to the 3 KHz required for the Asteroids game.

## POWER RESET AND INITIALIZATION

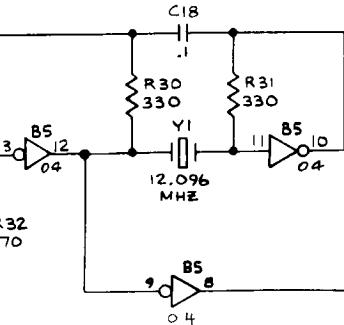

During initial power-up, the delayed charging of capacitor C25 causes a preset of flip-flop D4 and a clear of counter D5. This results in holding RESET input to the MPU low. When the charge of C25 reaches about 1.5 VDC, preset and clear inputs are removed. Counter D5 counts to 128 at 3 KHz rate and RESET is removed (goes high) from the input of the MPU. This allows the logic power input to the PCB to stabilize before allowing the MPU to begin its initialization routine.

If the MPU program is operating properly, the MPU address decoding circuitry will output the WDCLR (Watchdog clear) signal at predetermined intervals. This serves to clear counter D5 before it counts up to the state that will create the RESET condition. If the MPU program strays from its intended sequence and does not output the WDCLR signal, counter D5 will count up to the RESET state and cause the MPU to return to its initialization routine.

# DECODING CIRCUITRY

The address decoder performs the function of turning on or enabling the appropriate circuitry at the critical time, so that information can be transferred back and forth between the game circuitry and the MPU. The memory map below is for the Asteroids game.

If you are going to use the Automatic RAM/ROM Tester, please remember to remove MPU C3 and ground the WDOG DISABLE test point.
