

From the current-to-voltage converters, the signal is fed to two sample-and-hold circuits: One is non-inverted and the other is inverted. The non-inverted sample and hold consists of one stage of analog switch D12 and capacitor C98 for the X axis, and B12 and C106 for the Y axis. The inverting sample and hold consists of inverter E12, one stage of analog switch D12, and capacitor C119 for the X axis and B/C12, B12 and C118 for the Y axis.

The sample and hold circuits are controlled by SHCON (sample and hold control). SHCON is derived by gating 3-MHz from the microcomputer clock circuitry and VGCK\* from the vector generator's state generator. The result of these inputs insures that the non-inverted and inverted analog signals that are applied to the analog switches have sufficiently stabilized before being applied to the sample and hold capacitors.

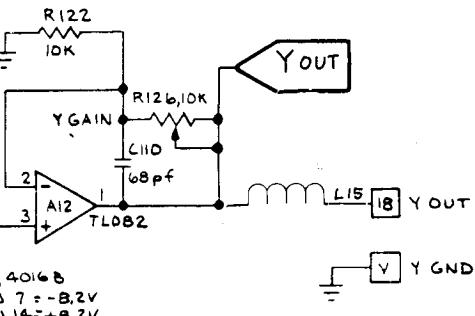

The output swing of SHCON is -8 to +8 VDC. When SHCON is high, the voltage charges or discharges the sample-and-hold capacitors to the X and Y analog voltage value. The voltages are then applied to the inputs of the second analog switch. These switches select either the non-inverted or inverted X-axis and Y-axis outputs. The outputs are then amplified by the second stages of C12 and A12 for an impedance-matched output to the X and Y inputs to the monitor. Since the monitor doesn't have field-adjustable X and Y gains, the gains are adjustable by variable resistors R120 and R126.

### Z Output

The Z axis video output receives six inputs. BVLD (beam valid), from the output of the vector generator's position counters, tells the Z axis to draw the line. BLANK (vector line blank), from the vector generator's state machine, tells the Z axis to stop drawing a line. SCALE0 thru SCALE3 (grey level shading scale), from the output of the vector generator's data latch, tells the Z axis the grey level shading of the line that is being drawn on the monitor.

When BVLD and BLANK are both high, a high is clocked through shift register K9 that turns transistor Q3 off. This allows the scale inputs to be passed through transistor Q2. When BLANK goes low, a low is clocked through K9, transistor Q3 turns on, and the signal is grounded at the base of transistor Q2.

The scale inputs at the base of transistor Q1 determine Q1's emitter voltage, during the line draw period. The SCALE0 thru SCALE3 resistors R36 thru R39, resistor R35, and resistor R40 result in a range of about +1.0 VDC when all are low and +4.0 VDC when all are high. The emitter of Q1 follows at about +1.7 to 4.7 VDC, while the emitter of transistor Q2 follows at about +1.0 to 4.0 VDC. This output is applied to the Z input of the monitor. Since there are brightness and contrast controls in the monitor, there are no adjustments in this circuit.

## VIDEO INVERTER

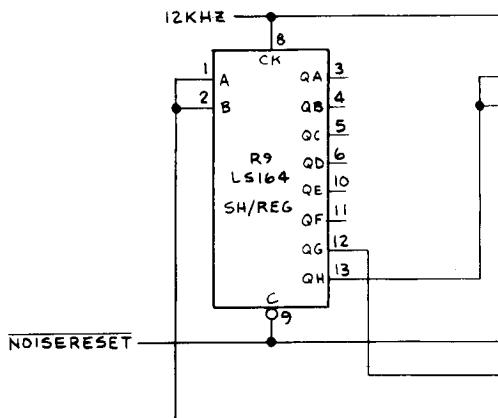

The video inverter circuitry is only used in a cocktail game. In an upright game, pin 19 is unconnected and therefore floats. When pin 19 floats, transistor Q16 is turned off and transistor Q17 is turned on. Therefore, INV is -8.2 VDC and NONINV is about +8.2 VDC. The result is a non-inverted X-axis and Y-axis output.

In a cocktail game, the wiring harness shorts connector J20's output pin 7 input pin 19. When the video of player 1 is being displayed, pins 7 and 19 are +5 VDC. This results in a non-inverted video output. When the video for player 2 is being displayed, pins 7 and 19 are grounded. This causes transistor Q16 to be turned on and Q17 to be turned off. Therefore, INV is +8.2 VDC and NONINV is -8.2 VDC. The result is an inverted X-axis and Y-axis output, causing the monitor's display to be upside down.

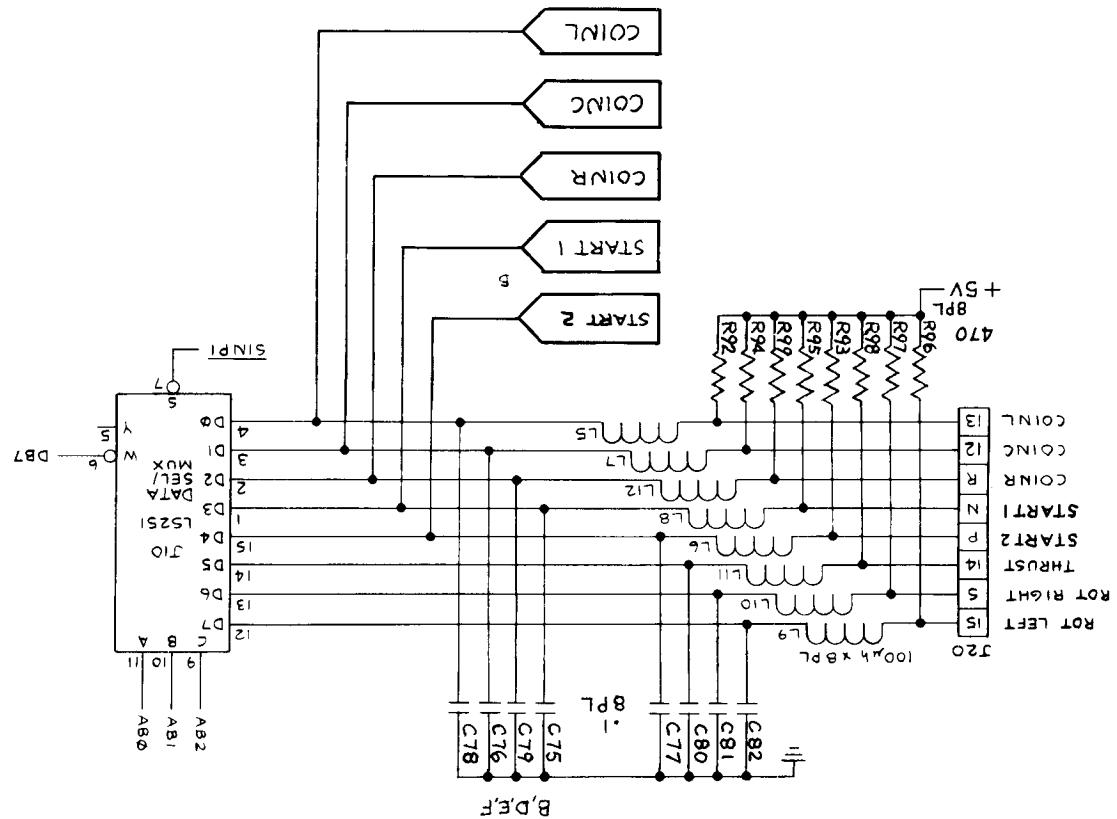

NOTE: FOR COUNTER P8, 9316 IS AN ACCEPTABLE SUBSTITUTE FOR 74LS161.

R9 and P9 generate random noise is filtered by P11 and produce rumble sound heard when thrusting.

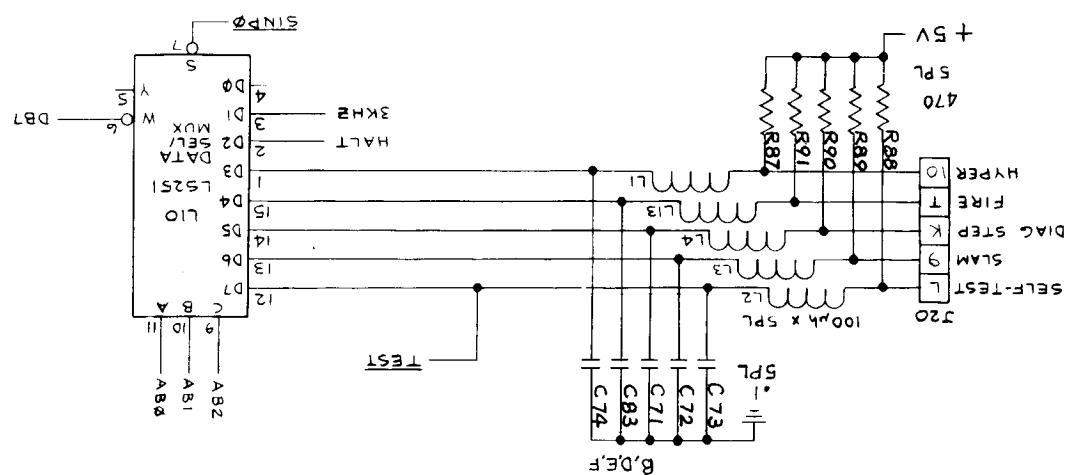

## OPTIONS INPUT CIRCUITRY

The coin door and some control panel switches are read by the MPU when SINP1 (switch selected by ABO thru AB2) is low. Input one enable (SINP1) is high when pulled to ground.

SLAM is a signal generated by the MPU to indicate the status of the anti-lam switch mounted on the coin door. The MPU reads HALT to determine the state of the vector generator. Some control panel switches are read by the MPU to initiate and control the game's self-test procedure. SLAM is a signal read by the MPU to activate when pulled to ground. DIAG STEP, 3 KHz, and SELF-TEST are active when pulled to ground. All inputs are read on DB7. Switch inputs are read on DB0 thru AB2 from the MPU. All inputs are selected by ABO (switch input zero enable) is low. Switches to be read on DB7 are read on DB0 thru AB2 from the MPU when SINP0 (switch selected by ABO thru AB2) is low. All inputs are read by the MPU when SINP0 (switch input zero enable) is low, SINP0 is high, and the MPU reads zero enable (SINP1) is high. The MPU reads zero enable (SINP1) is high, and the MPU reads zero enable (SINP1) is high.

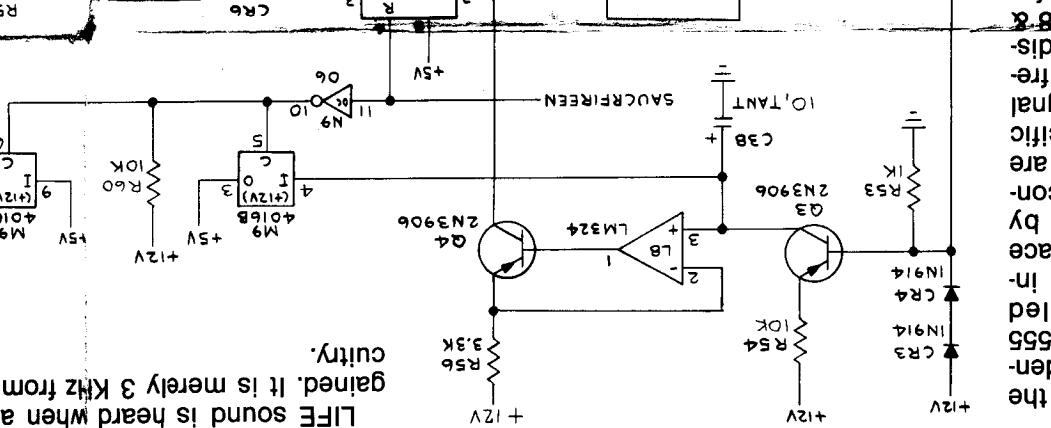

## PLAYER INPUT CIRCUITRY

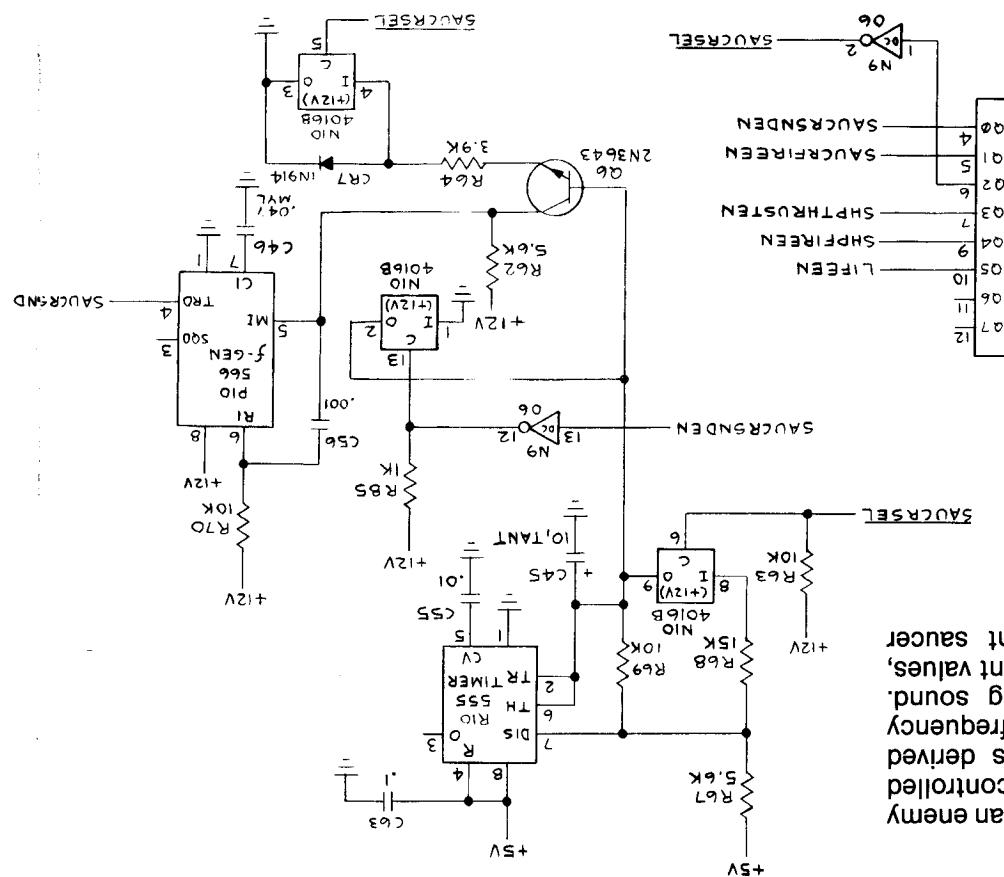

## OUTPUTS

The Fire sounds for the Saucer and the Space Ships are generated by two identical oscillating circuits. Each contain a 555 operated oscillator. The Saucer Fire sound is initiated by SAUCERFIREEN, and the Space ship oscillator by SHPFIREEN. Each of the Space ships are such a way that when the 555s is con-figured in such a way that they output a signal of a specific frequency and amplitude. This signal begins to decay immediately, both in frequency and amplitude. When the 555s is enabled, they output a signal that is con-figured in such a way that when the 555s is con-

M10 latches different sounds to enable different sounds.

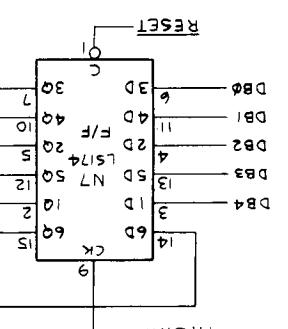

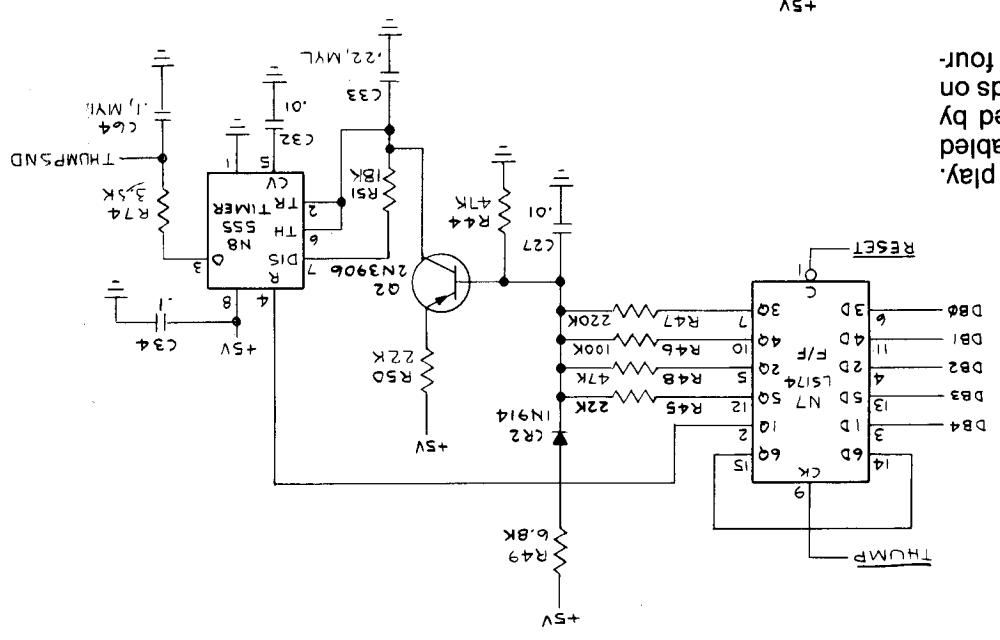

LIFE sound is heard when an ex-  
cited. It is merely 3 kHz from the  
SAUCER.

The SAUCER sound is heard when an enemy saucer appears. The 556 is a voltage-controlled oscillator. Its modulating voltage is derived from the 555. The 555 is a low frequency oscillator. The effect is a warbling sound.

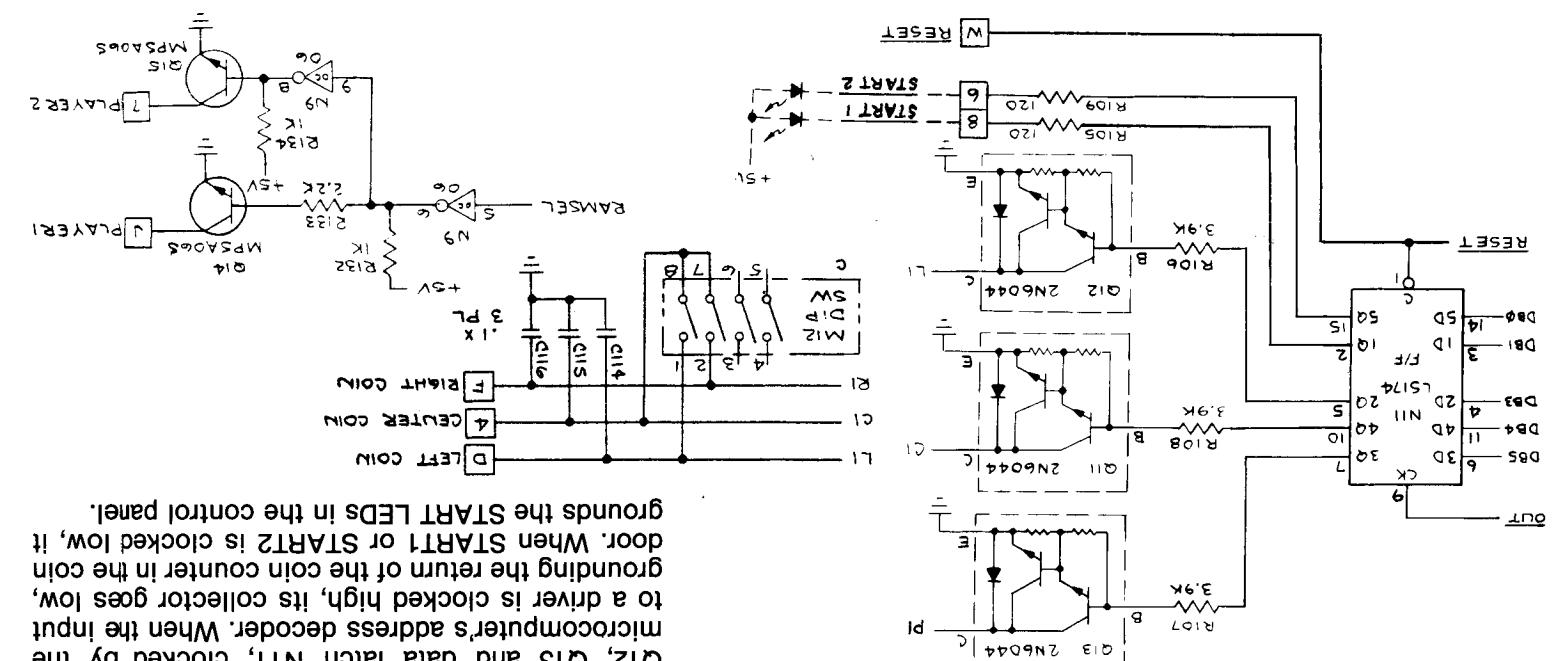

SAUCERSEL changes some component values in order to provide for 2 different saucer sounds.

The THUMP sound is heard through the speaker. The 555 is connected as an oscillator, enabled by N7 pin 2. The frequency is determined by its base voltage, which is derived from the four-bit code in N7.

## VIDEO OUTPUTS

This circuit consists of coin counter drivers Q11, Q12, Q13 and data latch N11, clocked by the microcomputer's address decoder. When the input to a driver is clocked high, its collector goes low, grounding the START LEDs in the control panel door. When START1 or START2 is clocked low, it grounds the START LEDs in the control panel door.

## LAMP, LED, AND COIN COUNTER OUTPUT

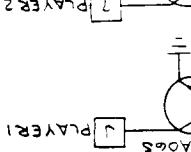

All sounds are mixed in 1/4 of P11. This is 1/4 of P11 and becomes Audio 2. These outputs to the phase signals provide a push-pull output to the audio section of the Regulator/Audio PCB.

X and Y Outputs

The video output circuit consists of three individual circuits; X axis, Y axis, and Z axis video output. The X and Y video output consists of a shift register and a summing amplifier. The Z axis video output consists of a current-to-video converter, two sample-and-hold registers, and a digital-to-analog converter. The DACs (D11 and D11) each receive binary numbers from the vector generator's position counters outputs. These numbers represent the location of the beam on the monitor. For the non-inverted X axis, the numbers range from 0 to 1023, where 0 is at the far left of the monitor screen, 512 is at the center, and 996 is at the top. When the X axis and Y axes are inverted, the monitor picture is turned upside down. This is used for a two-player cocktail game. The DACs convert these binary number inputs to current outputs. The DACs' current outputs are applied to the pin 6 inputs of current-to-voltage converters C12 and A12. The DACs convert these binary number inputs to current outputs. The DACs' current outputs are applied to the pin 6 inputs of current-to-voltage converters C12 and A12.
